### Abstract

Most often the mandibular anterior teeth are visible when a patient speaks or smiles. Congenitally missing mandibular central incisors demand restoration of both aesthetics and function. The restoration of these teeth pose challenges such as lack of sufficient space, inadequate bone and aesthetics. Proper diagnosis and treatment planning and a multidisciplinary approach are the key factors that play a role in satisfactory aesthetic and functional outcome. This case report discusses an interdisciplinary approach for the aesthetic and functional replacement of congenitally missing mandibular central incisors in a young adult patient.
