Abstract

Health of the oral cavity and its care is really important in maintaining proper masticatory function, digestion, phonation, appearance, and psychological well-being. When one or more than one tooth is lost due to any of the reason, it may adversely affect the oral health aesthetics being the most serious consequence for the patient and primary reason for which patient may come for prosthetic rehabilitation. Lazzara in 1989 was first one to introduce immediate implant in infected sockets after that this treatment has gained much more popularity.

Then Fuggazato in 2012 did a study comparing the placement of immediate implant in infected as well as in normal sockets where it was observed that both the treatment modalities gave no statistical difference and difference in survival rates.

This is a case report of a patient who reported to the department with the complaint of pain and pus discharge in lower front tooth region.
