ABSTRACT:

The implant restorative emergence profile (IREP) represents the contour of implant abutment/crown complex as it arises from the implant restorative platform and emerges from the peri-implant soft tissue. Ideally, the IREP contour should mimic that of an extracted tooth while supporting a harmonious, esthetic gingival architecture that mimics the surrounding natural dentition from level (facial and proximal) morphologic standpoint. Successful treatment of implants in the aesthetic zone requires proper shaping and conditioning of the surrounding soft tissue. There are various factors that should be kept in mind during planning before the surgical procedure to get optimum results. The purpose of this article is to compile these factors together that contribute in the maintenance of emergence profile and selection of various methods that can be used to optimise it.

KEYWORDS: emergence profile, implant restoration, pink esthetics
