**ABSTRACT**

The loss of maxillary central incisors has psychological, esthetic and functional implications. Multiple treatment options are available for replacing missing central incisors. The management demands a multidisciplinary approach involving the orthodontist, prosthodontist, and periodontist, Treatment planning requires considerations of a variety of clinical and non-clinical factors. This clinical report attempts to demonstrate an approach involving progressive mesial substitution and reanatomization of maxillary lateral incisors, canines, and premolars to manage the missing maxillary central incisors.
